Section 1 : Coding

1. Problem Statement:

Sam is developing a geometry application and needs a class for trapezoid calculations. Create a "Trapezoid" class implementing a "ShapeInput" interface with a method to input trapezoid dimensions.

Also, implement a "ShapeCalculator" interface with methods to compute area and perimeter. In the "Main" class, instantiate Trapezoid, gather user input, and display the calculated area and perimeter with two decimal places.

Note

Area of Trapezoid = $(1/2) * (base1 + base2) * height$

Perimeter of Trapezoid = $base1 + base2 + side1 + side2$

Input Format

The first line of input is a double-point value representing base1 of the trapezoid.

The second line of input is a double-point value representing base2 of the trapezoid.

The third line of input is a double-point value representing the height of the trapezoid.

The fourth line of input is a double-point value representing side1 of the trapezoid.

The fifth line of input is a double-point value representing side2 of the trapezoid.

Output Format

The output displays the two lines of the calculated area (double type) and perimeter (double type) of the trapezoid, each rounded to two decimal places in the following format:

"Area of the Trapezoid: <<calculated area>>".

Perimeter of the Trapezoid: <<calculated perimeter>>".

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 1.0

2.0

1.0

3.0

1.0

Output: Area of the Trapezoid: 1.50

Perimeter of the Trapezoid: 7.00

Answer

```
import java.util.Scanner;
```

```
// You are using Java
```

```
interface ShapeInput {  
    void getInput();  
}
```

```
interface ShapeCalculator {  
    double calculateArea();  
    double calculatePerimeter();  
}
```

```
class Trapezoid implements ShapeInput, ShapeCalculator {  
    double base1, base2, height, side1, side2;
```

```
    public void getInput() {  
        Scanner sc = new Scanner(System.in);  
        base1 = sc.nextDouble();  
        base2 = sc.nextDouble();  
        height = sc.nextDouble();  
        side1 = sc.nextDouble();  
        side2 = sc.nextDouble();  
    }
```

```
    public double calculateArea() {  
        return 0.5 * (base1 + base2) * height;  
    }
```

```
    public double calculatePerimeter() {  
        return base1 + base2 + side1 + side2;  
    }  
}
```

```
public class Main {  
    public static void main(String[] args) {  
        Trapezoid trapezoid = new Trapezoid();  
        trapezoid.getInput();
```

```
        double area = trapezoid.calculateArea();  
        double perimeter = trapezoid.calculatePerimeter();
```

```
        System.out.println("Area of the Trapezoid: " + String.format("%.2f", area));
```

```
        System.out.println("Perimeter of the Trapezoid: " + String.format("%.2f",  
        perimeter));  
    }  
}
```

Status : Correct

Marks : 10/10

2. Problem Statement

Maria, an online store owner, is looking to implement a pricing system that calculates the final price of products after applying discounts. She needs a program that takes the original price of a product and the discount percentage as input and computes the final discounted price. The discount is applied as a percentage of the original price. Maria wants to ensure that the final price is formatted to display exactly two decimal places.

Implement this functionality using the PriceCalculator interface and the DiscountCalculator class.

Input Format

The first line of input consists of the original price (a double value).

The second line of input consists of a discount percentage (a double value).

Output Format

The output displays the final price after the discount, adhering to the following format: "Final Price after discount: \$[final_price]".

Here, [final_price] should be replaced with the calculated final price, formatted as a currency value with two decimal places.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 100.0
10.0

Output: Final Price after discount: \$90.00

Answer

```
import java.util.Scanner;

interface PriceCalculator {
    double calculatePrice(double originalPrice, double discount);
}

class DiscountCalculator implements PriceCalculator {
    public double calculatePrice(double originalPrice, double discount) {
        return originalPrice - (originalPrice * discount / 100);
    }
}

class Main {
    public static void main(String[] args) {
        Scanner scanner = new Scanner(System.in);
        double originalPrice = scanner.nextDouble();
        double discount = scanner.nextDouble();
        PriceCalculator calculator = new DiscountCalculator();
        double finalPrice = calculator.calculatePrice(originalPrice, discount);
        System.out.printf("Final Price after discount: $%.2f%n", finalPrice); //
        Formats output to 2 decimal places
    }
}
```

3. Problem Statement:

Ray is developing a tax calculation program in Java. The program includes an interface named TaxCalculator with a method to calculate tax based on salary. The SimpleTaxCalculator class implements this interface and determines the tax to be paid based on the salary amount using progressive tax slabs.

Your task is to implement this system. The program first takes an integer T representing the number of test cases, followed by T salary values. For each salary, calculate the total tax to be paid based on the following

progressive tax rules:

For the first 50,000 of salary, the tax rate is 5%. For the next 50,000 (i.e., from 50,001 to 1,00,000), the tax rate is 10%. For any amount above 1,00,000, the tax rate is 20%. (That is, only the amount above 1,00,000 is taxed at 20%.)

Example

Input

3

78000

110000

23000

Output

5300

9500

1150

Explanation

For Salary Rs. 78,000

$$\text{Tax} = 0.1 * (78,000 - 50,000) + 0.05 * 50,000 = 5,300$$

For Salary Rs. 1,10,000

$$\text{Tax} = 0.2 * (110000 - 100000) + 0.1 * 50,000 + 0.05 * 50,000 = 9,500$$

For Salary Rs. 23,000

$$\text{Tax} = 0.05 * 23,000 = 1,150$$

Input Format

The first line of the input consists of an integer, T, representing the number of test cases.

The next T lines of the input consist of a single integer, representing the annual

salary of an individual, separated by a line.

Output Format

The output displays the calculated tax as an integer for each test case, separated by a line.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 2

100

300

Output: 5

15

Answer

```
import java.util.Scanner;
```

```
interface TaxCalculator {  
    int calculateTax(int salary);  
}
```

```
class SimpleTaxCalculator implements TaxCalculator {  
    public int calculateTax(int salary) {  
        double tax = 0;  
  
        if (salary <= 50000) {  
            tax = salary * 0.05;  
        } else if (salary <= 100000) {  
            tax = 50000 * 0.05 + (salary - 50000) * 0.10;  
        } else {  
            tax = 50000 * 0.05 + 50000 * 0.10 + (salary - 100000) * 0.20;  
        }  
    }  
}
```

```
    return (int) tax;  
}
```

```
class Main {  
    public static void main(String[] args) {
```

```

Scanner scanner = new Scanner(System.in);
int T = scanner.nextInt();

TaxCalculator taxCalculator = new SimpleTaxCalculator();

for (int i = 0; i < T; i++) {
    int salary = scanner.nextInt();
    int tax = taxCalculator.calculateTax(salary);
    System.out.println(tax);
}

scanner.close();
}
}

```

4. Problem Statement

Alex and Bob are designing a control system for household appliances, and one of the appliances is a washing machine. You want to create a program to help them that models the washing machine as a motor and calculates its electricity consumption based on its capacity.

Define an interface named Motor with the following methods:

void run() double consume(double capacity)

Create a class called WashingMachine that implements the Motor interface.

In the WashingMachine class:

Implement the run() method to print "Washing machine is running." Implement a consume() method to print "Washing machine is consuming electricity." Implement the consume(double capacity) method to calculate the electricity consumption (in kWh) of the washing machine based on its capacity. The formula for electricity consumption is (capacity * 0.05).

Input Format

The input consists of a double value representing the capacity of the washing machine in kW.

Output Format

The first line of output prints "Washing machine is running."

The second line prints "Washing machine is consuming electricity."

The third line prints "Electricity consumption: X kWh" where X is a double value, rounded off to two decimal places, representing the electricity consumption.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 2.5

Output: Washing machine is running.

Washing machine is consuming electricity.

Electricity consumption: 0.13 kWh

Answer

```
import java.util.Scanner;
```

```
interface Motor {  
    void run();  
    double consume(double capacity);  
}
```

```
class WashingMachine implements Motor {  
    public void run() {  
        System.out.print("Washing machine is running. ");  
    }  
    public void consume() {  
        System.out.print("Washing machine is consuming electricity. ");  
    }  
    public double consume(double capacity) {  
        return capacity * 0.05;  
    }  
}
```

```
public class Main {
```

```
public static void main(String[] args) {  
    Scanner scanner = new Scanner(System.in);  
  
    WashingMachine washingMachine = new WashingMachine();  
  
    double capacity = scanner.nextDouble();  
  
    washingMachine.run();  
    washingMachine.consume();  
  
    double consumption = washingMachine.consume(capacity);  
    System.out.printf("Electricity consumption: %.2f kWh", consumption);  
    scanner.close();  
}  
}
```
